

DO NOT USE THESE PROJECTS - THESE ARE JUST EXAMPLES

Intermediate Project Example — “FutureClass”

FutureClass is a digital learning platform designed to help students prepare for the future of education through smarter collaboration, organization, and personalized learning tools. As classrooms become increasingly digital, many students still struggle to manage assignments, communicate with classmates, and stay productive across multiple apps and platforms. FutureClass brings these tools together into one streamlined experience focused on the future of learning.

The platform allows students to create study groups, organize assignments, share notes, and communicate in real time with classmates. Users can build subject-specific workspaces where they can upload resources, schedule study sessions, and track upcoming deadlines. The project focuses on creating a simple, modern, and accessible experience for students learning in an increasingly technology-driven world.

Possible features could include:

- Secure student accounts and authentication
- Shared calendars and assignment tracking
- Real-time messaging and collaboration
- Uploading notes, study guides, and resources
- AI-powered study recommendations
- Mobile-friendly and responsive design

Participants building a project like this might use:

- React, Next.js, or HTML/CSS/JavaScript
- Firebase or Supabase for authentication and databases
- Node.js or Python for backend functionality
- Tailwind CSS for styling and responsive layouts

This is a strong intermediate-level project because it demonstrates:

- Full-stack development
- User authentication systems

- Database integration
- Real-world usability
- Modern UI/UX design
- Collaboration-focused technology

Projects at the intermediate level do not need to be extremely advanced. A clean, functional, and well-executed project with a strong connection to the theme can stand out just as much as a highly technical submission.

Intermediate Project Example — “CareerSync”

CareerSync is an AI-powered platform designed to help students prepare for the future workforce by analyzing their interests, skills, and learning habits to recommend personalized career paths and educational opportunities. As technology rapidly changes the job market, many students feel unprepared for careers that may not even exist yet. CareerSync helps bridge that gap by giving students insight into emerging industries and future-focused skills.

Users can complete skill assessments, explore different career fields, and receive recommendations for courses, certifications, and projects that align with future industry trends such as AI, cybersecurity, renewable energy, and robotics. The platform could also include resume-building tools and interview preparation resources tailored toward modern careers.

Possible features could include:

- AI-generated career recommendations
- Skill and interest assessments
- Personalized learning roadmaps
- Resume and portfolio builders
- Future job trend dashboards
- Internship and scholarship discovery tools

Participants building a project like this might use:

- React or Next.js
- Firebase or PostgreSQL
- OpenAI APIs or recommendation algorithms
- Python or Node.js backend systems
- Data visualization libraries

This is a strong intermediate-level project because it demonstrates:

- AI integration
- Personalized user experiences
- Database management
- Real-world impact
- Strong connection to the future-focused theme

Intermediate Project Example — “EcoGrid”

EcoGrid is a smart energy-monitoring platform that helps households understand and reduce their environmental impact through real-time electricity usage tracking and predictive energy recommendations. As the world moves toward renewable energy and sustainable living, technology will play a major role in helping people make smarter energy decisions.

The platform allows users to monitor appliance usage, visualize household energy consumption, and receive suggestions for reducing waste during peak hours. The system could also simulate how adding solar panels, electric vehicles, or smart-home devices would affect long-term energy costs and carbon emissions.

Possible features could include:

- Real-time energy usage dashboards
- Predictive electricity cost analysis
- Carbon footprint tracking
- Smart-home integration simulations
- Personalized sustainability recommendations
- Data visualizations and reports

Participants building a project like this might use:

- React, Vue, or Flutter
- Python or Node.js backend services
- APIs for weather and energy data
- Firebase or MongoDB
- Charting and analytics libraries

This is a strong intermediate-level project because it demonstrates:

- Data-driven application design
- Sustainability-focused innovation
- Interactive dashboards
- API integration

- A clear connection to future technology and environmental challenges
